

DEV StrokePatchD – matched adaptive local views

One crop policy is shared by every real/fake source; only complete valid words are routed to the global discriminator.

1. One word image: adaptive count + stratified placement

2. The exact same sampler is applied to all five sources

3. What StrokePatchD actually sees

Six crops from the example above (representative contents shown):

Important: a patch is intentionally incomplete. StrokePatchD judges whether its local stroke statistics look real; it is not asked to read or validate the whole word.

4. Patch-only critic and correct discriminator routing
